## Lecture 17

Saad Mneimneh

---

---

---

---

---

---

---

## Diagram of Reality and Desire

- $\alpha$  is the reality
- $\beta$  is what is desired
- The diagram  $RD_{\beta}(\alpha)$  is the diagram of reality and desire:

Saad Mneimneh

---

---

---

---

---

---

---

## Diagram of Reality and Desire

(for better visualization)

- Extended  $\alpha$ : 0, +3, -2, -1, +4, -5, 6
- Extended  $\beta$ : 0, +1, +2, +3, +4, +5, 6

Saad Mneimneh

---

---

---

---

---

---

---

## Definition

Two reality edges on the same cycle *converge* if they are traversed in the same direction (either clockwise or counterclockwise) on the cycle.

Example:

(+3,+2) and (-1,-4) converge

(0,-3) and (+3,+2) diverge

---

---

---

---

---

---

---

---

## Reversals and $c(\alpha)$

Let  $\rho$  be a reversal defined by two reality edges  $e$  and  $f$ , then:

- If  $e$  and  $f$  belong to different cycles,  $c(\alpha\rho) = c(\alpha) - 1$
- If  $e$  and  $f$  belong to the same cycle and converge,  $c(\alpha\rho) = c(\alpha)$
- If  $e$  and  $f$  belong to the same cycle and diverge,  $c(\alpha\rho) = c(\alpha) + 1$

---

---

---

---

---

---

---

---

## Another lower bound

- Let  $\rho_1, \dots, \rho_t$  be such that  $\alpha\rho_1 \dots \rho_t = \beta$ , then:

$$\begin{array}{l} c(\alpha\rho_1) - c(\alpha) \leq 1 \\ c(\alpha\rho_1\rho_2) - c(\alpha\rho_1) \leq 1 \\ \dots \\ c(\alpha\rho_1 \dots \rho_t) - c(\alpha\rho_1 \dots \rho_{t-1}) \leq 1 \end{array} \quad \rightarrow \quad c(\alpha\rho_1 \dots \rho_t) - c(\alpha) = t - c(\alpha) \leq t$$

- Let  $t = d(\alpha)$ , then  $\boxed{d(\alpha) \geq n + 1 - c(\alpha)}$

---

---

---

---

---

---

---

---

## Better lower bound

- The lower bound  $n + 1 - c(\alpha)$  is better than  $b(\alpha)/2$ .
- For most signed permutations, it comes very close to the actual reversal distance.
- It does not always work. We cannot always choose two divergent edges (doing so will increase the number of cycles by 1 each time and achieve the exact bound).
- To understand why, we need to define some concepts.

---

---

---

---

---

---

---

## Good / Bad cycles

The easy stuff first...

- A cycle is **good** iff it has two reality edges that diverge
- A cycle is **bad** iff all its reality edges converge
- A cycle is **proper** iff it contains more than two edges (we will only look at these).

---

---

---

---

---

---

---

## Interleaving

- Assume the special way of drawing  $RD(\alpha)$ 
  - either the counterclockwise circle where reality edges are on the circumference and desire edges are chords
  - or reality edges are on the line and desire edges on top
- Two cycles interleave iff a desire edge of one crosses a desire edge of the other
- In general we can define this using intervals without assuming a special way of drawing  $RD(\alpha)$

---

---

---

---

---

---

---

## Interleaving

A and E interleave

B and C interleave

C and D interleave

B and D interleave

---

---

---

---

---

---

---

---

## Components

We have three components:

{F}

{A, E}

{B, C, D}

---

---

---

---

---

---

---

---

## Good / Bad components

We have three components:

{F} : good

{A, E} : bad

{B, C, D} : good

---

---

---

---

---

---

---

---

## Classification of bad components

---

---

---

---

---

---

---

---

## Hurdles

A bad component is a hurdle iff it does not separate between any two components

---

---

---

---

---

---

---

---

## Super Hurdles

*F* is a super hurdle,  
it protects *E*

All other hurdles are  
Simple hurdles

---

---

---

---

---

---

---

---

## Fortress

A signed permutation  $\alpha$  is called a fortress iff  $RD(\alpha)$  has an odd number of hurdles and all of them are super hurdles

The smallest fortress,  
with 3 super hurdles

Saad Mneimneh

---

---

---

---

---

---

---

---

## New lower bound

$$d(\alpha) \geq n + 1 - c(\alpha) + h(\alpha)$$

Any reversal  $\rho$  acts on two reality edges, and can "destroy" at most two hurdles (by definition, hurdles cannot separate between hurdles), therefore

$$\Delta h = h(\alpha\rho) - h(\alpha) \geq -2$$

three cases:

- $\Delta c = 1$ , then  $\rho$  acts on a good cycle and  $\Delta h = 0$  (no hurdles destroyed),  $\Delta(c-h) = 1$
- $\Delta c = 0$ , then  $\rho$  acts on a bad cycle and  $\Delta h \geq -1$  (at most one hurdle destroyed),  $\Delta(c-h) \leq 1$
- $\Delta c = -1$ , then  $\Delta h \geq -2$  anyway (at most two hurdles destroyed),  $\Delta(c-h) \leq 1$

Saad Mneimneh

---

---

---

---

---

---

---

---

## Exact traversal distance

$$d(\alpha) = n + 1 - c(\alpha) + h(\alpha), \alpha \text{ non-fortress}$$

$$d(\alpha) = n + 1 - c(\alpha) + h(\alpha) + 1, \alpha \text{ fortress}$$

where  $h(\alpha)$  is the number of hurdles

Saad Mneimneh

---

---

---

---

---

---

---

---

## Approach

- We will achieve the lower bound  $n + 1 - c(\alpha) + h(\alpha)$  for a non-fortress permutation  $\alpha$
- Each time we will find a reversal  $\rho$  such that  $c(\alpha\rho) - h(\alpha\rho) = c(\alpha) - h(\alpha) + 1$
- Call such a reversal a safe reversal
- $c(\alpha) - h(\alpha)$  can be at most  $n+1$  (when  $\alpha = \beta$ ); therefore, we will perform only  $n+1 - c(\alpha) + h(\alpha)$  reversals

---

---

---

---

---

---

---

---

## Safe reversal Kind I

- A reversal  $\rho$  defined by two divergent reality edges of a good cycle that does not lead to the creation of bad components
- Safe: increases  $c$  by 1, keeps  $h$  unchanged; therefore,  $c(\alpha\rho) - h(\alpha\rho) = c(\alpha) - h(\alpha) + 1$
- Fact: if we have a good component, then there exists a safe reversal of kind I (we are not going to prove this)

---

---

---

---

---

---

---

---

## Safe reversal Kind II (hurdle merging)

- Define two opposite hurdles  $A$  and  $B$  such that the number of hurdles between  $A$  and  $B$  is the same on either sides of the circle.
- A reversal  $\rho$  defined by two reality edges of two opposite hurdles (i.e. the number of hurdles must be even)
- $\rho$  destroys two hurdles which become a good component with any non-hurdle that separates them.
- $\rho$  does not create new hurdles.
- Safe: decreases  $c$  by 1, decreases  $h$  by 2; therefore,  $c(\alpha\rho) - h(\alpha\rho) = c(\alpha) - h(\alpha) + 1$

---

---

---

---

---

---

---

---

## Illustration

Saad Mneimneh

---

---

---

---

---

---

---

---

## Safe reversal Kind III (hurdle cutting)

- A reversal  $\rho$  defined by two convergent reality edges of a bad cycle in a simple hurdle when number of hurdles is odd.
- $\rho$  destroys the hurdle (makes it good component), and does not create new hurdles (otherwise it is a super hurdle), and results in even number of hurdles.
- Safe: keeps  $c$  unchanged, decreases  $h$  by 1; therefore,  $c(\alpha\rho) - h(\alpha\rho) = c(\alpha) - h(\alpha) + 1$

Saad Mneimneh

---

---

---

---

---

---

---

---

## Non-fortress

- If  $\alpha$  is not a fortress, then we can always find a safe reversal
- Proof:
  - If there is a good component, then there is a kind I safe reversal.
  - If there are no good components and the number of hurdles is even, then there is a Kind II safe reversal (hurdle merging)
  - If there are no good components and the number of hurdles is odd, then there is a simple hurdle (otherwise  $\alpha$  is a fortress), and there is a Kind III safe reversal (hurdle cutting). After that point the number of hurdles is always even.

Saad Mneimneh

---

---

---

---

---

---

---

---

## Algorithm

given distinct  $\alpha$  and  $\beta$

**repeat**

if there is a good component in  $RD_{\beta}(\alpha)$   
**then** pick a Kind I reversal

**else if**  $h(\alpha)$  is even  
**then** pick a Kind II reversal (merging two opposite hurdles)

**else if**  $h(\alpha)$  is odd  
**then** pick a Kind III reversal (cutting simple hurdle)

**until**  $\alpha = \beta$

Saad Mneimneh

---

---

---

---

---

---

---

---

## What if $\alpha$ is a fortress

- Then we have an odd number of hurdles non of which is simple
  - We cannot cut a super hurdle since this will create a new hurdle
  - We can merge two super hurdles (not opposite), but there is a danger of creating a new hurdle!
- FACT: merging two super hurdles in a fortress with  $h \neq 3$  super hurdles results in a fortress with  $h - 2$  super hurdles.
- Therefore, we create a new hurdle only when we have a forest with 3 super hurdles resulting is a distance of  $n + 1 - c(\alpha) + h(\alpha) + 1$  for a fortress permutation.
- This is optimal for a fortress because any fortress has to have one unsafe reversal, but we will not prove it here.

Saad Mneimneh

---

---

---

---

---

---

---

---

## Algorithm

given distinct  $\alpha$  and  $\beta$

**repeat**

if there is a good component in  $RD_{\beta}(\alpha)$   
**then** pick a Kind I reversal

**else if**  $h(\alpha)$  is even  
**then** pick a Kind II reversal (merging two opposite hurdles)

**else if**  $h(\alpha)$  is odd and there is a simple hurdle  
**then** pick a Kind III reversal (cutting simple hurdle)

**else** //fortress  
merge any two hurdles (this will result in a fortress if  $h(\alpha) \neq 3$ )

**until**  $\alpha = \beta$

Saad Mneimneh

---

---

---

---

---

---

---

---

## Running time (initialization of structure)

- Constructing  $RD(\alpha)$  takes  $O(n)$  time (determine reality and desire edges)
- Finding cycles can be done in  $O(n)$  time
- For each cycle we have to determine whether it is good or bad, this takes  $O(n)$  time for each cycle for a total of  $O(n^2)$  time
- Interleaving of cycles can be done in  $O(n^2)$  time by examining every pair of desire edges
- Determining good and bad components, non-hurdles, simple hurdles, and super hurdles can be done in  $O(n)$  time
- So far  $O(n^2)$  time

---

---

---

---

---

---

---

---

## Running time (cont.)

- The most time consuming part is identifying whether a safe reversal of Kind I exists
- Since a reversal is defined by two edges, we have  $O(n^2)$  reversals to try
- For each reversal we have to see whether a bad component will be created (this can be done in  $O(n^2)$  time as discussed above by computing  $RD(\alpha\rho)$ )
- Therefore, we spend  $O(n^4)$  time
- This is performed at most  $n$  times yielding an  $O(n^5)$  time algorithm
